PERFORMANCE OF A TRANSONIC FAN STAGE DESIGNED FOR A LOW MERIDIONAL VELOCITY RATIO

by Royce D. Moore, George W. Lewis, Jr., and Walter M. Osborn

Lewis Research Center

SUMMARY

This report presents both the aerodynamic design parameters and the performance of a transonic fan stage having a meridional velocity ratio of 0.8 across the tip of the stage. The stage was designed for a pressure ratio of 1.57 at a flow of 29.5 kilograms per second and a tip speed of 426 meters per second. Detailed radial surveys were obtained over the stable operating range from 50 to 100 percent of design speed.

The stage peak efficiency (0.81) at design speed occurred at a pressure ratio of 1.58 and a flow of 28.7 kilograms per second. The stage stall margin was 11 percent, based on conditions at peak efficiency and stall. Rotor peak efficiency (0.84) occurred at a pressure ratio of 1.61 and the same flow as stage peak efficiency.

INTRODUCTION

The axial-flow fan and compressor research program for advanced airbreathing engines being conducted at Lewis is primarily directed toward reducing the size and weight of fans and compressors while maintaining high levels of performance. In support of this objective, experimental studies are being conducted to evaluate the effects of blade solidity, blade aspect ratio, blade loading, area margin above choke, blade airfoil shape, weight flow per unit annulus area, velocity ratio, and blade spacing on efficiency and flow range. The aerodynamic performance of the axial-flow fan stage designed for a stage tip velocity ratio of 0.8 is presented herein. Performance of a similar stage having a tip meridional velocity ratio of 1.0 was reported in reference 1. The velocity ratio was varied by changing the stage tip contour while maintaining the same hub contour. Both stages were designed for a pressure ratio of 1.57 and a tip speed of 425 meters per second. This report presents the aerodynamic design parameters and the overall and blade-element performance. Data were obtained at a near-stall point for six rotative speeds from 50 to 100 percent of design speed and over the stable operating

range of 70, 90, and 100 percent of design speed.

Blade-element data were obtained for the rotor and the stator at 11 radial positions. The stage discussed in this report has been designated stage 20-17 (rotor 20 and stator 17). The data in this report are presented in tabular and in machine-plotted form. The symbols and equations are given in appendixes A and B, and the definitions and units used for the tabular data are presented in appendix C.

AERODYNAMIC DESIGN

Three computer programs (refs. 2 and 3) were used to design this compressor stage: the streamline analysis program, the blade geometry program, and the blade coordinate program. Only a brief description of each is presented herein.

The streamline-analysis program was used to calculate the flow-field parameters at several axial locations, including planes approximating the blade leading and trailing edges for both the rotor and stator. The weight flow, rotative speed, flow path geometry, and radial distributions of total pressure are inputs in this program. Total loss, which is calculated within the program, is based on a calculated shock loss and a profile loss. Profile loss as a function of diffusion factor and radial position is an input. The program accounts for both streamline curvature and entropy gradients; boundary-layer blockage factors are also included.

The distribution of velocity vector, total pressure, and total temperature calculated in the streamline-analysis program are used in the blade-geometry program to compute blade-geometry parameters. The blade-geometry parameters are used in the blade coordinate program (ref. 4) to compute blade elements on conical surfaces passing through the blade. The blade elements are then stacked on a line passing through their centers of gravity, and Cartesian blade coordinates, which are used directly in fabrication, are computed.

The overall design parameters for stage 20-17 are listed in table I, and the flow path is shown in figure 1. This stage was designed for an overall pressure ratio of 1.57 at a weight flow of 29.5 kilograms per second (196.4 kg/sec/m^2 of annulus area). The design tip speed was 426 meters per second. The inlet relative Mach number is 1.4 at the rotor tip. Since the stage was designed for a tip solidity of 1.3 for both rotor and stator, the rotor had 44 blades with an aspect ratio of 2.5, and the stator had 48 blades with an aspect ratio of 2.4.

The blade-element design parameters for rotor 20 are presented in table II. This rotor was designed for a radially constant total-pressure ratio of 1.60. The stator blade-element design parameters are given in table III. The blade geometry is presented in table IV for rotor 20 and in table V for stator 17. Both the rotor and stator used multiple-circular-arc blade shapes.

APPARATUS AND PROCEDURE

Compressor Test Facility

The compressor stage was tested in the Lewis single-stage compressor facility (described in detail in ref. 4 and shown in fig. 2 herein). Atmospheric air enters the test facility at an inlet on the roof of the building and flows through the flow measuring orifice and into the plenum chamber upstream of the test stage. It then passes through the experimental compressor stage and into the collector from which it is exhausted to the atmosphere.

Test Stage

Photographs of the rotor and stator are shown in figures 3 and 4. Each rotor blade has a vibration damper located at about 57 percent of span from the outlet rotor tip. The maximum thickness of the damper was 0.215 centimeter. The radial tip clearance of the rotor was a nominal 0.050 centimeter at ambient, nonrotating conditions. The axial spacing between the rotor hub trailing edge and the stator hub leading edge was 3.428 centimeters, to provide for instrumentation between rotor and stator.

Instrumentation

The compressor weight flow rate was measured using a calibrated thin-plate orifice. The orifice temperature was determined from an average of two Chromel/constantan thermocouples. Orifice pressures were measured by calibrated transducers.

Radial surveys of the flow were made upstream of the rotor, between the rotor and stator, and downstream of the stator (fig. 1). Photographs of the survey probes are shown in figure 5. Total pressure, total temperature, and flow angle were measured with the combination probe (fig. 5(a)), and the static pressure was measured with an 8° C-shaped wedge probe (fig. 5(b)). Each probe was positioned with a null-balancing, stream-directional-sensitive control system that automatically alined the probe to the direction of flow. The thermocouple was Chromel/constantan. The probes were alined in an air-calibration tunnel. Two combination probes and two wedge static probes were used at each of the three measuring stations.

Inner- and outer-wall static-pressure taps were located at the same axial stations as the survey probes. The circumferential locations of both types of survey probes and of the inner- and outer-wall static-pressure taps are shown in figure 6. The combination probe downstream of the stator (station 3) traversed circumferentially one stator

blade passage (7.5^0) counterclockwise from the nominal value shown. An electronic speed counter, in conjunction with a magnetic pickup, measured rotative speed (rpm). Strain gages mounted on both the rotor and stator blades monitored stresses and vibrations. The estimated errors of the data based on inherent accuracies of the instrumentation and recording system are as follows:

Weight flow, kg/sec	±0.3
Rotative speed, rpm	±30
Flow angle, deg	±1
Temperature, K	±0.6
Rotor-inlet total pressure, N/cm ²	±0.01
Rotor-outlet total pressure, N/cm ²	±0.10
Stator-outlet total pressure, N/cm ²	±0.10
Rotor-inlet static pressure, N/cm ²	±0.04
Rotor-outlet static pressure, N/cm ²	±0.07
Stator-outlet static pressure, N/cm ²	±0.07

An indication of the consistency of the data can be observed by comparing the integrated weight flows at each measuring station with the orifice weight flow in table VI.

Test Procedure

The stage survey data were taken over a range of weight flows from maximum flow to the near stall. At 70, 90, and 100 percent of design speed, radial surveys were taken at five weight flows. At 50, 60, and 80 percent of design speed, radial surveys were taken for the near-stall weight flow only. Data were recorded at 11 radial positions for each speed and weight flow.

At each radial position the combination probe behind the stator was traversed circumferentially to nine locations across the stator gap. The wedge probe was set at mid-gap because previous studies showed that the static pressure across the stator gap was constant. The pressure, temperature, and flow angle were recorded at each circumferential position. At the last circumferential position pressure, temperature, and flow angle were also recorded at stations 1 and 2. All probes were then traversed to the next radial position, and the circumferential traverse procedure was repeated.

At each of the six rotative speeds the back pressure on the stage was increased by closing the sleeve valve in the collector until a stall was indicated by a sudden drop in stage-outlet total pressure. This pressure was measured by a probe at midpassage and was recorded on an X-Y plotter. Stall was corroborated by large increases in the blade stresses on both rotor and stator along with a sudden increase in noise.

Calculation Procedure

The measured total temperatures and pressures were corrected for Mach number and streamline slope. These corrections were based on the instrument probe calibrations given in reference 5. The stream static pressures were corrected for Mach number and streamline slope based on an average calibration for the wedge probes used.

Because of the physical construction of the C-shaped static-pressure wedges, it was not possible to obtain static-pressure measurements at 5, 10, and 95 percent of span. The static pressure at 95 percent span was obtained by assuming a linear variation in static pressure between the values at the inner wall and the probe measurement at 90 percent span. A similar variation was assumed between the static-pressure measurements at the outer wall and the 30 percent span to obtain the static pressure at 5 and 10 percent span.

At each radial position for station 3, averaged values of the nine circumferential measurements of pressure, temperature, and flow angle were obtained. The nine total temperatures were mass averaged to obtain the stator-outlet total temperature. The nine total pressures were energy averaged (i. e., converted to their enthalpy equivalent and then mass-averaged). The measured pressures, temperatures, and flow angles were used to calculate axial and tangential velocities at each circumferential position. Mass averages of these velocities were used to calculate the flow angles at each radial position presented herein. To obtain the overall performance, the radial values of total temperatures were mass-averaged, and radial values of total pressures were energy-averaged. At each measuring station, the integrated weight flow was computed based on the survey data. The data, measured at the three measuring stations, were translated to the blade leading and trailing edges by the method presented in reference 4.

The weight flow at stall was obtained in the following manner: During operation at near-stall, the sleeve valve was closed in small decrements. After each decrement the weight flow was obtained. The weight flow obtained just before stall occurred is called the stall weight flow. The pressure ratio at stall was obtained by extrapolating the total pressure obtained from the survey data to the stall weight flow.

Orifice weight flow, total pressures, static pressures, and temperatures were all corrected to sea-level conditions based on the rotor inlet conditions.

RESULTS AND DISCUSSION

The results from this investigation will be presented in three main sections. The overall performances for the rotor and the stage are given first. Radial distributions of several performance parameters are then presented for the rotor and stator followed by the blade-element data. Because the data presented are machine plotted, an oc-

casional point will be omitted because it falls outside the range of the parameters shown in the figure. A brief comparison of these results and those from a high-velocity ratio stage is included. The plotted data, together with some additional performance parameters, are also tabulated: The overall performance data are given in table VI; and the blade-element data are presented for the rotor in table VII and for the stator in table VIII. The definitions and units used in the tables are listed in appendix C.

Overall Performance

The overall performance for rotor 20 and for stage 20-17 are presented in figures 7 and 8 for speeds from 50 to 100 percent of design. Design-point values are shown as solid symbols in both figures. The stall line (dashed line) shown in figure 8 was determined using the method discussed in the section Calculation Procedure.

Rotor. - The design-speed peak efficiency for rotor 20 was 0.838, which occurred at a weight flow of 28.7 kilograms per second. Although the pressure ratio at peak efficiency was only slightly greater than the design value, it occurred at a flow less than the design value. At 70 percent of design speed, efficiencies up to 0.87 were obtained for this rotor.

Stage. - At design speed the stage peak efficiency of 0.813 occurred at the same weight flow as peak efficiency for the rotor. The measured pressure ratio (1.582) was slightly higher than the design value (1.574). And the calculated stall margin was approximately 11 percent based on conditions at stall and peak efficiency. At the lower speeds efficiencies ranged up to 0.84.

Radial Distributions

The radial distributions of several parameters are presented for design speed in figure 9 for rotor 20 and in figure 10 for stator 17. The data are presented for three weight flows: maximum flow, peak efficiency, and near stall. The design values are shown by the solid symbols. A line is faired through the peak efficiency data. Temperature-rise efficiency, temperature ratio, pressure ratio, suction-surface incidence angle, meridional velocity ratio, deviation angle, total loss parameter, total loss coefficient, and diffusion factor are presented as functions of percent span from the blade tip.

Rotor. - As the weight flow was reduced, the pressure ratio and temperature ratio increased across the entire rotor blade span with the larger increases occurring in the tip region. The blade loading (diffusion factor) also continued to increase with decreasing weight flow. The effect of the damper (57 percent span) on efficiency is evident at

all three weights.

At the peak efficiency weight flow of 28.7 kilograms per second, the pressure ratio was greater than design from the tip to 50 percent span and was less than design from there to the hub. The efficiency shows a large deviation from design from the region of the damper to the hub. There is a radial shift in the flow toward the blade tip with higher than design meridional velocity ratios from the tip to 30 percent span.

Stator. - At the peak efficiency condition the stator deviation angles were essentially equal to design except in the hub and tip regions. In the stator hub region, there was a large increase in losses from the 90 to 95 percent span indicating probable separation. This occurred at all three flows. The losses in the tip region were significantly greater than design.

Variation with Incidence Angle

The variation of selected rotor and stator blade-element performance parameters with incidence angle are presented in figures 11 and 12. The data are presented for 70, 90, and 100 percent of design speed at blade elements located at 5, 10, 30, 50, 70, 90, and 95 percent spans. Design values are shown by solid symbols.

Rotor. - The rotor blade elements were designed for a suction surface incidence angle of zero. At the design incidence angle the pressure ratio was higher than design at 5, 10, and 30 percent spans apparently because the flow turns more in these regions as indicated by the less-than-design deviation angles. At 50 percent span the pressure ratio and deviation angles are equal to design values. At 70, 90, and 95 percent span the blades under turned the flow (higher than design deviation angles); therefore the pressure ratio was less than design.

At 5 and 10 percent span the minimum loss incidence angle was not defined. At 30 percent span the minimum loss was approximately equal to design; however, it occurred at less than design incidence angle. At 50, 70, and 90 percent span minimum loss occurred near design incidence angle of zero; however, the values were significantly greater than design values. At 95 percent span minimum loss occurred at a greater than design incidence angle and its value was also greater than design.

Stators. - Except at the 5 and 95 percent span locations, minimum losses were equal to or less than design and generally occurred at negative incidence angles. At the 5 percent span location, there were high losses and deviation angles over the incidence angle range. At the 10 and 95 percent span, there was an increase in losses at the low incidence angles. Deviation angles exceeded design values at 5, 10, 90, and 95 percent span locations.

Comparison with Higher-Velocity-Ratio Stage

The performance of stage 20-17 may be compared with that of stage 11-4 of reference 1, which had a velocity ratio of 1.0 across the stage tip. The velocity ratio was reduced to 0.8 in stage 20-17 by changing the outer flow path contour while keeping the same inner flow path contour. The radial distribution of blade solidity, blade chord, leading and trailing edge thicknesses, maximum thickness, X-factors, and rotor blade minimum area ratios were held constant between the stages. The axial locations of the transition point and maximum thickness were also held constant. The stages were designed for a pressure ratio of 1.57 at a nominal specific flow of 198 kilograms per second per square meter of annulus area and a nominal tip speed of 425 meters per second.

The change in stage tip meridional velocity ratio had very little effect on overall performance. At design speed and flow the stage efficiency was essentially the same for both stages. The pressure ratio was slightly higher for the stage with the 1.0 velocity ratio. The same changes were observed for the two rotors. The stall margin based on conditions at the peak efficiency point and the stall point for the 1.0 velocity ratio stage was 19 percent but was only 11 percent for the 0.8 velocity ratio stage. However, if stall margin is based on conditions at the design flow point and stall point, both stages would have a stall margin of 19 percent, and the efficiency for the 0.8 velocity ratio stage would be less than 0.5 percentage point below its peak value.

SUMMARY OF RESULTS

This report presents both the aerodynamic design parameters and the performance of a transonic fan stage having a meridional velocity ratio of 0.8 across the stage tip. This stage was designed for a pressure ratio of 1.57 at a flow of 29.5 kilograms per second and a tip speed of 426 meters per second. Detailed radial surveys of the flow conditions in front of the rotor, between the rotor and stator, and downstream of the stator were made over the stable operating flow range at rotative speeds from 50 to 100 percent of design speed. This investigation yielded the following principle results:

1. At design speed the stage peak efficiency of 0.81 occurred at a flow of 28.7 kilograms per second and a pressure ratio of 1.58. Stage stall margin was 11 percent based on the flow and pressure ratio at peak efficiency and stall.
2. At design speed a rotor peak efficiency of 0.84 occurred at a pressure ratio of 1.61 and the same flow as for stage peak efficiency.
3. At the design incidence angle the measured rotor pressure ratio in the tip re-

gion was higher than design as a result of more turning (deviation angles less than design). In the hub region there was less turning and lower pressure ratio.

APPENDIX B

EQUATIONS

Suction-surface incidence angle:

$$i_{ss} = (\beta'_c)_{LE} - \kappa_{ss} \quad (B1)$$

Mean incidence angle:

$$i_{mc} = (\beta'_c)_{LE} - (\kappa_{mc})_{LE} \quad (B2)$$

Deviation angle:

$$\delta^o = (\beta'_c)_{TE} - (\kappa_{mc})_{TE} \quad (B3)$$

Diffusion factor:

$$D = 1 - \frac{V'_{TE}}{V'_{LE}} + \left| \frac{(rV_\theta)_{TE} - (rV_\theta)_{LE}}{(r_{TE} + r_{LE})\sigma(V'_{LE})} \right| \quad (B4)$$

Total loss coefficient:

$$\bar{\omega} = \frac{(P'_{id})_{TE} - P'_{TE}}{P'_{LE} - p_{LE}} \quad (B5)$$

Profile loss coefficient:

$$\bar{\omega}_p = \bar{\omega} - \bar{\omega}_s \quad (B6)$$

Total loss parameter:

$$\frac{\bar{\omega} \cos (\beta'_m)_{TE}}{2\sigma} \quad (B7)$$

Profile-loss parameter:

$$\frac{\bar{\omega}_p \cos(\beta_m')_{TE}}{2\sigma} \quad (B8)$$

Adiabatic (temperature rise) efficiency:

$$\eta_{ad} = \frac{\left(\frac{P_{TE}}{P_{LE}}\right)^{(\gamma-1)/\gamma} - 1}{\frac{T_{TE}}{T_{LE}} - 1} \quad (B9)$$

Momentum-rise efficiency:

$$\eta_{mom} = \frac{\left(\frac{P_{TE}}{P_{LE}}\right)^{(\gamma-1)/\gamma} - 1}{\frac{(UV_\theta)_{TE} - (UV_\theta)_{LE}}{T_{LE} g J C_p}} \quad (B10)$$

Equivalent weight flow:

$$\frac{W\sqrt{\theta}}{\delta} \quad (B11)$$

Equivalent rotative speed:

$$\frac{N}{\sqrt{\theta}} \quad (B12)$$

Mass flow per unit annulus area:

$$\frac{W\sqrt{\theta}}{\frac{\delta}{A_{an}}} \quad (B13)$$

Mass flow per unit frontal area:

$$\frac{\frac{w\sqrt{\theta}}{\delta}}{A_f} \quad (B14)$$

Head-rise coefficient:

$$\frac{gJC_p T_{LE}}{U_{tip}^2} \left[\left(\frac{P_{TE}}{P_{LE}} \right)^{(\gamma-1)/\gamma} - 1 \right] \quad (B15)$$

Flow coefficient:

$$\left(\frac{V_z}{U_{tip}} \right)_{LE} \quad (B16)$$

Stall margin:

$$SM = \left[\frac{\left(\frac{P_{TE}}{P_{LE, stall}} \right) \times \left(\frac{w\sqrt{\theta}}{\delta} \right)_{ref}}{\left(\frac{P_{TE}}{P_{LE}} \right)_{ref} \times \left(\frac{w\sqrt{\theta}}{\delta} \right)_{stall}} - 1 \right] \times 100 \quad (B17)$$

Polytropic efficiency:

$$\eta_p = \frac{\ln \left(\frac{P_{TE}}{P_{LE}} \right)^{(\gamma-1)/\gamma}}{\ln \left(\frac{T_{TE}}{T_{LE}} \right)} \quad (B18)$$

APPENDIX C

DEFINITIONS AND UNITS USED IN TABLES

ABS	absolute
AERO CHORD	aerodynamic chord, cm

1. Report No. NASA TP 1298	2. Government Accession No.	3. Recipient's Catalog No.	
4. Title and Subtitle PERFORMANCE OF A TRANSONIC FAN STAGE DESIGNED FOR A LOW MERIDIONAL VELOCITY RATIO		5. Report Date November 1978	
		6. Performing Organization Code	
7. Author(s) Royce D. Moore, George W. Lewis, Jr., and Walter M. Osborn		8. Performing Organization Report No. E-8994	
		10. Work Unit No. 505-04	
9. Performing Organization Name and Address National Aeronautics and Space Administration Lewis Research Center Cleveland, Ohio 44135		11. Contract or Grant No.	
		13. Type of Report and Period Covered Technical Paper	
12. Sponsoring Agency Name and Address National Aeronautics and Space Administration Washington, D. C. 20546		14. Sponsoring Agency Code	
15. Supplementary Notes			
16. Abstract This report presents the aerodynamic performance and design parameters of a transonic fan stage designed for a meridional velocity ratio of 0.8 across the tip of the stage, a pressure ratio of 1.57, a flow of 29.5 kilograms per second, and a tip speed of 426 meters per second. Radial surveys were obtained over the stable operating range from 50 to 100 percent of design speed. The measured, peak efficiency (0.81) of the stage occurred at a pressure ratio of 1.58 and a flow of 28.7 kilograms per second.			
17. Key Words (Suggested by Author(s)) Compressors Turbomachinery		18. Distribution Statement Unclassified - unlimited STAR Category 07
